

HOW THIS GIBBY EVOLVED BELOW: embryonic processes

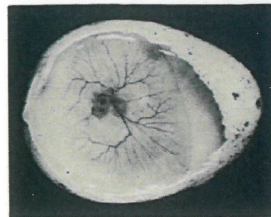

...inside of the shell might attract predators.

INCUBATION:

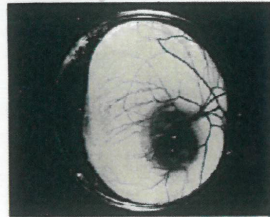

FOUR WEEKS OF GROWTH INSIDE THE EGG

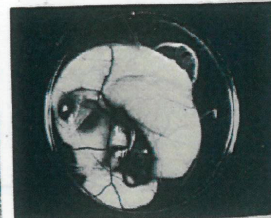

NEW-LAID TURKEY'S EGG The germ cell from which the embryo will grow is visible only as a pale spot (lower left) on the surface of the yolk.

DAY 5 The embryo, surrounded by a network of blood vessels bringing nourishment from the yolk, begins to take shape; the head is on the right.

DAY 12 Main regions of the limbs are well formed; the beak takes shape; the leg has five toes (not seen), one of which will disappear.

DAY 15 An eye (top left) shows clearly; main light feathers (dark patches, lower centre) have developed; toes have claws (not seen).

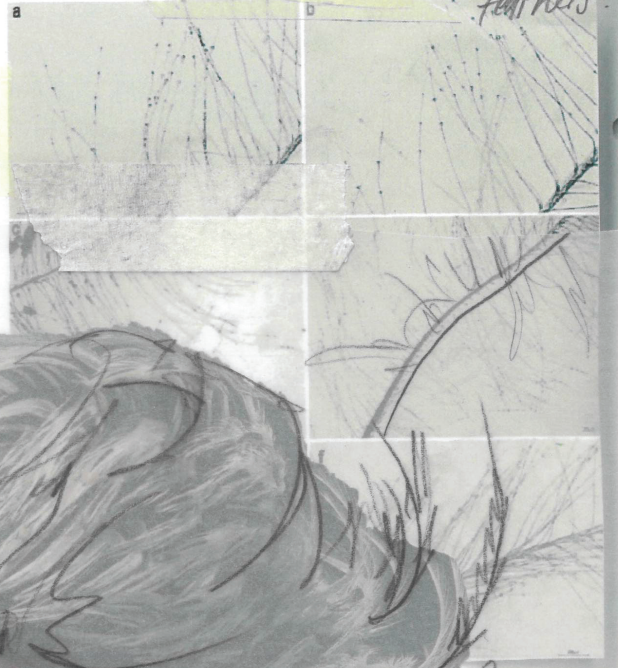

DAY 23 The embryo is fully formed, with its egg-tooth (white bump on beak); growth of features already present is the main chance in the last week.

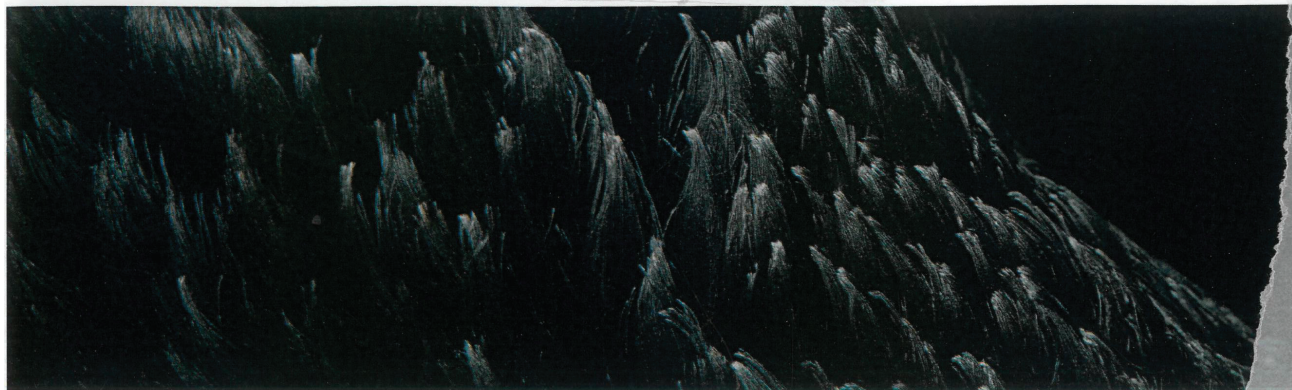

DAY 26 The chick has chipped its egg-tooth and struggles with its growth and struggles to break through the shell.
